Adoption

This paper presents an empirical investigation to determine the important factors influencing on adoption of biofuels from consumer's perspective. The study designs a questionnaire in Likert scale and distributes it among 211 randomly selected people who use green products in city of Tehran, Iran. Cronbach alpha is calculated as 0.812, which is well above the acceptable level. Using principle component with Varimax rotation, the study has determined five important factors including social commitment, product usefulness, infrastructure, management approach and customer oriented, which influence the most on adaptation of biofuels.

1. Introduction

One of the most essential questions in today's day-to-day activities is to learn more on how to take care of the environment. Every day, more news appear about the effects of global warming on people's lives. These days, we hear more from media on unpleasant incidents such as shortage of water supply, starvation, air pollution, etc. Fossil fuels are blamed as the most important causes of air pollution and Biofuel is an alternative solution to reduce the burden of fossil fuels. During the past several decades, many have argued as to whether or not it is possible to reach a replacement of environment friendly fuels, which would be also cost effective. In other words, many have tried to answer a simple question "Does it pay to be green?" (Hart & Ahuja, 1996). Bhat (1999) investigated the relationships between the environmental performances and financial performances of some U.S. firms. The environmental performance in this survey was measured in pollution in pounds per sales revenue while the financial performance was computed in terms of profit margins and stock market performance. Bhat performed an indebt investigation into more than 230 firms and found that lower pollution per sales revenue had a positive effect on the profit margins and stock performance. Pollution in their survey was also determined to maintain a direct effect on environmental compliance, spills and different other legal infractions. Stefan and Paul (2008) investigated the relationship between emissions reduction and

company performance on data from S&P 500 firms. They reported that “efforts to prevent pollution and reduce emissions drop to the ‘bottom line’ within one to two years of initiation and that those firms with the highest emission levels stand the most to gain”. Orsato (2006) presented a model for categorizing generic kinds of competitive environmental strategies to help managers determine and rank areas of organizational action, and to optimize the overall economic return on environmental investments and making them into sources of competitive advantage. King and Lenox (2001) performed a survey and reported that despite the fact that there are some evidences on relationship between lower pollution and higher financial valuation, a firm's fixed characteristics and strategic position may create some barriers on this association. Biofuels extracted from low-input high-diversity mixtures of native grassland perennials may give more usable energy, bigger greenhouse gas reductions, and less agrichemical pollution per hectare than alternative ones such as corn grain ethanol or soybean biodiesel (Tilman et al., 2006) and the primary objective of the present survey is to learn how to cope with this type of fuels.

2. The proposed study

This paper presents an empirical investigation to determine important factors influencing on adoption of biofuels in consumer's perspective. The study designs a questionnaire in Likert scale and distributes it among 211 randomly selected people who use green products in city of Tehran, Iran. Cronbach alpha is calculated as 0.812, which is well above the acceptable level. Table 1 presents the results of KMO and Bartlett's tests. Table 2 demonstrates the results of the summary of communalities. Table 3 presents the implementation of principal component analysis after rotation. Fig. 1 demonstrates Scree plot of the factors in our survey.

3. Discussion and conclusion

In this paper, we have presented an empirical investigation to study the effects of various factors influencing on the adaptation of biofuels in Iran. The survey has detected five factors. The first factor, social commitment, consists of five sub-factors. Attention to environment appears to be one of the most important items, which must be considered in both governmental as well as public sector (D'Souza et al., 2008). To reach this objective, it is essential to raise public awareness, which is also the second factor detected in our survey. There is no doubt that public transportation plays essential role for reaching better environment system. Of course, this should be accompanied with a good corporate social responsibility and green shopping behavior, which are other important factors and it must be considered as social commitment. The findings of this part of the survey are consistent with findings reported by Gan et al. (2008).

Product usefulness is the second factor in our survey, which consists of six factors. The value created by client is the most important factor followed by the perceived usefulness. In order to reach this

objective, it is necessary to see cheaper prices of biofuel products and increase consumer's profitability. Government may intervene in pricing alternative fuel products and provide necessary information for customer. Infrastructure is the third most important factor influencing on biofuel adaptation with four sub-factors. Any fuel change must be supported by industry and technical equipment must be available. In addition, it is necessary to have appropriate channels with effective logistics (Gurau & Ranchhod, 2005).

Management approach is another factor in our survey, which consists of four sub-factor. The first step for management team to adopt biofuel is to setup an appropriate administrate knowledge. It is also necessary to determine whether or not the new fueling system is technically feasible (Hu et al., 2008; Brennan & Owende, 2010). On the other hand, technology now changes rapidly and it is important to cope with the changes and perform an analysis on how to cope with market change.

Customer orientation is the last component of our survey with five sub-factors. Improving the quality of life would be first objective of the survey followed by appropriate customization of the product and subjective norms. Moreover, any customer orientation must be accompanied with sufficient personal knowledge of customers. Finally, product life cycle is the last important factor influencing the most on customer orientation. In fact, a short life cycle for a particular fuel product may discourage customer for green fuel usage. Development of biofuel may offer other advantages such as reduction on poverty in agriculture (Peskett et al., 2007). However, others argue such claims. According to Car (2011), in the forest products marketing literature, many people study the environmental perspectives of business strategy as the nexus between economic growth and sustainable development. Car (2011) presented a three-stage evolutionary framework driven by the government regulations, environmental standards, private initiatives, environmental NGOs and consumers. The study suggested that an environmental marketing strategy may create competitive opportunities for companies, but some environmental practices, such as forest certification, might not improve competitive performance unless they are located with the firm's resources and the external environment as part of the strategy. This part of Car's findings are consistent with findings of this study in terms of management approach.
